Service manuals: 54100A/D. HP/Agilent 54100A/D Service Manual. The present invention relates to an apparatus and method for image processing of a captured image, and more specifically, to an apparatus and method for image processing capable of removing unnecessary color from an image. Imaging devices (image sensors) such as cameras using an image sensor are available for capturing a color image and a moving image. Such an imaging device captures the color image and the moving image with light that has passed through a color filter of a predetermined color. A color filter of three primary colors is widely used for the imaging device. A color filter of three primary colors is provided for each of pixels of a three-line Bayer array. More specifically, there are a total of three colors, namely, red (R), green (G), and blue (B) per pixel. This pattern is repeated in a staggered manner across the imaging device. A color of a pixel may be obtained by subtracting a blue component from a red component or a green component, for example. The pixel level colorization method is a well-known technique for processing the color image captured by the imaging device. In the pixel level colorization method, the colorization is performed on a pixel-by-pixel basis. The pixel level colorization method is described in Japanese Unexamined Patent Application Publication No. 2001-257620, for example. In the pixel level colorization method, red components, blue components, and green components in a plurality of input image frames are sequentially subtracted from one another to obtain a difference signal. The difference signal is encoded to obtain a difference image frame (color image). Alternatively, the red components, green components, and blue components in the plurality of input image frames are sequentially multiplied by different coefficients to obtain a multiplication signal. The multiplication signal is encoded to obtain a multiplication image frame (color image).
